- Final Exam
 - Apr. 10 at 12:00-15:00
 - Location TBA

C and Programming Basics

Lecture 2

Today:

- The compilation process
- Differences between Python and C
- Variable declaration and strong typing
- The memory model: data vs. address

The Compilation Process

In Python:

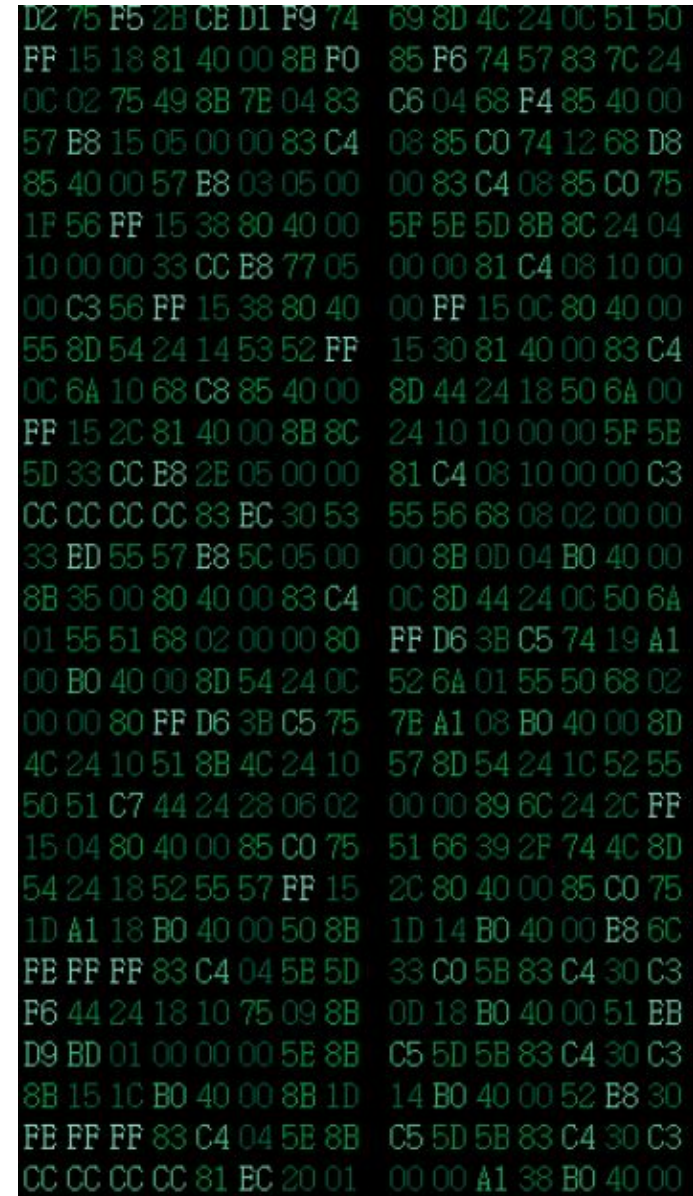

But in C, there is an extra step:

- Interpreter simulates one instruction at a time
- Compiler translates entire program in advance

Machine Language

- A *machine language* can be processed directly by a computer
 - A program is a sequence of instructions
 - Each instruction code (*opcode*) is represented by a number
 - No variable names or subroutine names in machine language!
- Each number is represented in binary
- Machine languages are very hard for humans to write and understand

Hexadecimals

- Binary: each digit has two possible values: 0 or 1
- Decimals: ten possible values per digit: 0-9
- Hexadecimal: each digit has sixteen possible values: 0-9, A-F
 - Convenient: one hexadecimal digit represents 4 binary digits (bits)

BIN	DEC	HEX

Assembly Language

- A high-level language compared to machine languages, but lower-level compared to C
- Abstract operation codes as mnemonics
- Abstract memory addresses as labels (variable names)
- An *assembler* translates mnemonics and labels into machine language

```

.subsections_via_symbols
```

Assembly for “Hello World!” program

Language Translators

- Python's *interpreter* speaks to the machine
 - translate and run instructions one at a time
- C code is *compiled* using gcc
 - translate all instructions before running
 - faster performance at run time
 - no interactive interpreter in C
- Programming languages are formal and lack the richness of human languages
 - If a program is nearly, but not quite, syntactically correct, then it will not compile
 - The compiler will not “figure it out”

Differences Between Python and C

- Python

- `print arg1, . . .`
- `arg1 = raw_input()`
- `int, float, str, bool`
- variables declared during execution
- `and, or, not`
- `if-elif-else`
- `for i in range(n)`
- indented blocks
- lists may grow/shrink

- C

- `printf(format, arg1, . . .)`
- `scanf(format, &arg1, . . .)`
- `int, float, char`
- variables declared at compile time (strong vars)
- `&&, ||, !`
- `if { } else if { } else { }`
- `for (i = 0; i < n; i++) { }`
- `{ blocks in curly braces }`
- arrays are fixed in size

Variable Declaration

In C programs, you must declare your variables before using them.

```
int main ( ) {  
    int a = 5;  
    int b = 17;  
    printf("The sum of %d + %d is %d\n", a, b, a+b);  
}
```

The code `int a = 5` declares that you will use an integer variable named “a”, which has an initial value of 5

Strong Typing

- In C, you can't change the type of a variable
 - Once an `int`, always an `int`
 - It is possible to change types in Python
- gcc reserves space for your variables in memory
 - Usually 4 bytes for an `int` or a `float`
 - Usually 8 bytes for a `long long` or a `double`
 - Usually 1 byte for a `char`
- The type of variable is important because all data is represented by 0's and 1's

Printing Characters

```
#include <stdio.h>
```

```
int main() {  
    char c = '0';  
    printf("%c\n", c);  
}
```

Output:

0

Printing Characters

```
#include <stdio.h>
```

```
int main() {  
    char c = '0';  
    printf("%c\n", c);  
}
```

Interpret the variable c as a character

Output:

0

Printing Characters

```
#include <stdio.h>
```

```
int main() {  
    char c = '0';  
    printf("%d\n", c);  
}
```

Interpret the variable c as a **decimal integer**

Printing Characters

```
#include <stdio.h>
```

```
int main() {  
    char c = '0';  
    printf("%d\n", c);  
}
```

Output:

48

Interpret the variable c as a **decimal integer**

Memory Model

- Each var stored in a unique memory location
 - its *address*
 - represented by a number (an integer, usually)
- Thus a variable is composed of 3 things:
 - its type
 - its value
 - its address
- Some programs need the address explicitly
 - Addresses can be stored in variables
 - A variable that contains the address of another variable is called a *pointer*

Using an Address

```
#include <stdio.h>

int main ( ) {
    int a = 0, b = 0;
    scanf("%d", &a);
    scanf("%d", &b);
    printf("The sum of %d + %d is %d\n", a, b, a+b);
}
```

- The input function `scanf()` needs to know *where* to store the input integer
- “&a” represents the address of a
